    c.shrink_to_fit();

    return c;
}
```

Geo Notes

Center of mass

System of points(2D/3D): Mass weighted average of points.

Frame(2D/3D): Get middle point of each segment solve as previously.

Triangle: Average of vertices.

2D Polygon: Compute **signed** area and center of mass of triangle $((0,0), p_i, p_{i+1})$. Then solve as system of points.

Polyhedron surface: Solve each face as a 2D polygon (be aware of $(0,0)$) then replace each face with its center of mass and solve as system of points.

Tetrahedron(Triangular pyramid): As triangles, its the average of points.

Polyhedron: Can be done as 2D polygon, but with tetrahe-

dralization instead of triangulation.

Pick's Theorem

Given a polygon without self-intersections and all its vertices on integer coordinates in some 2D grid. Let A be its area, I the number of points with integer coordinates strictly inside the polygon and B the number of points with integer coordinates in the border of the polygon. The following formula holds: $A = I + \frac{B}{2} - 1$.

Miscellaneous

LIS

```
multiset<int> S;
for(int i = 0; i < n; i++){
    auto it = S.upper_bound(a[i]); // low for inc
    if(it != S.end()) S.erase(it);
    S.insert(a[i]);
}
ans = S.size();
```

Burnside's Lemma

Let (G, \oplus) be a finite group that acts on a set X . It should hold that $e_g * x = x$ and $g_1 * (g_2 * x) = (g_1 \oplus g_2) * x, \forall x \in X, g_1, g_2 \in G$. For each $g \in G$ let $X^g = \{x \in X \mid g * x = x\}$. The number of orbits its given by:

$$|X/G| = \frac{1}{|G|} \sum_{g \in G} |X^g|$$

Wilson's Theorem

$(n-1)! \equiv -1 \pmod n \iff n$ is prime

Fibonacci

- $F_{n-1}F_{n+1} - F_n^2 = (-1)^n$
- $F_{n+k} = F_kF_{n+1} + F_{k-1}F_n$
- $GCD(F_n, F_m) = F_{GCD(n,m)}$
- $F_n = \frac{(\frac{1+\sqrt{5}}{2})^n - (\frac{1-\sqrt{5}}{2})^n}{\sqrt{5}}$

Lucas's Theorem

For non-negative integers m and n and a prime p , the following congruence holds:

$$\binom{m}{n} \equiv \prod_{i=0}^k \binom{m_i}{n_i} \pmod p$$

where m_i is the i -th digit of m in base p . $\binom{a}{b} = 0$ if $a < b$.

Kirchhoff's Theorem

Laplacian matrix is $L = D - A$, where D is a diagonal matrix with vertex degrees on the diagonals and A is adjacency matrix.

The number of spanning trees is any cofactor of L . i -th cofactor is determinant of the matrix gotten by removing i -th row and column of L .

Multigraphs

In $D[i][i]$ all loops are excluded. $A[i][j]$ = number of edges from i to j .

Directed multigraphs

$D[i][i]$ = indegree of i minus the number of loops at i . $A[i][j]$ = number of edges from i to j .

The number of oriented spanning trees rooted at a vertex i is the determinant of the matrix gotten by removing the i th row and column of L .

Matroid

Let X set of objects, $I \subseteq 2^X$ set of independent sets such that:

- $\emptyset \in I$
- $A \in I, B \subseteq A \implies B \in I$
- Exchange axiom, $A \in I, B \in I, |B| > |A| \implies \exists x \in B \setminus A : A \cup \{x\} \in I$
- $A \subseteq X$ and I and I' are maximal independent subsets of A then $|I| = |I'|$

Then (X, I) is a matroid. The combinatorial optimization problem associated with it is: Given a weight $w(e) \geq 0 \forall e \in X$, find an independent subset that has the largest possible total weight.

Matroid intersection

```

// Input two matroids (X, I_a) and (X, I_b)
// output set I of maximum size, I \in I_a and I \in I_b
set<> I;
while(1){
    for(e_i : X \ I)
        if(I + e_i \in I_a and I + e_i \in I_b)
            I = I + e_i;
    set<> A, T; queue<> Q;
    for(x : X) label[x] = MARK1;
    for(e_i : X \ I){
        if(I + e_i \in I_a)
            Q.push(e_i), label[e_i] = MARK2;
        else{
            for(x such that I - x + e_i \in I_a)
                A[x].push(e_i);
        }
        if(I + e_i \in I_b)
            T = T + {e_i}
        else{
            for(x such that I - x + e_i \in I_b)
                A[e_i].push(x);
        }
    }
    if(T.empty()) break;
    bool found = false;
    while(!Q.empty() and !found){
        auto e = Q.front(); Q.pop();
        for(x : A[e]) if(label[x] == MARK1){
            label[x] = e; Q.push(x);
            if(x \in T){
                found = true; put = 1;
                while(label[x] != MARK2){
                    I = put ? (I + x) : (I - x);
                }
            }
        }
    }
}

```

```

        put = 1 - put;
    }
    I = I + x;
    break;
}
}
}
if(!found) break;
}
return I;

```

Where $\text{path}(e) = [e]$ if $\text{label}[e] = \text{MARK2}$, $\text{path}(\text{label}[e]) + [e]$ otherwise.

Matroid Union

Given k matroids over the same set of objects $(X, I_1), (X, I_2), \dots, (X, I_k)$ find $A_1 \in I_1, A_2 \in I_2, \dots, A_k \in I_k$ such that $i \neq j, A_i \cap A_j = \emptyset$ and $|\bigcup_{i=1}^k A_i|$ is maximum. Matroid union can be reduced to matroid intersection as follows.

Let $X' = X \times \{1, 2, \dots, k\}$, ie, k copies of each element of X with different colors. $M1 = (X', Q)$ where $B \in Q \iff \forall 1 \leq i \leq k, \{x \mid (x, i) \in B\} \in I_i$, ie, for each color, B is independent. $M2 = (X', W)$ where $B \in W \iff i \neq j \implies \neg((x, i) \in B \wedge (x, j) \in B)$, ie, each element is picked by at most one color.

Intersection of $M1$ and $M2$ is the answer for the combinatorial problem of matroid union.

Notes

When we repeat something and each time we have probability p to succeed then the expected number of tries is $\frac{1}{p}$, till we

succeed.

Small to large

Trick in statement If k sets are given you should note that the amount of different set sizes is $O(\sqrt{s})$ where s is total size of those sets. And no more than \sqrt{s} sets have size greater than \sqrt{s} . For example, a path to the root in Aho-Corasick through suffix links will have at most $O(\sqrt{s})$ vertices.

gcd on subsegment, we have at most $\log(a_i)$ different values in $\{\text{gcd}(a_j, a_{j+1}, \dots, a_i) \text{ for } j < i\}$.

From static set to expandable. To insert, create a new set with the new element. While there are two sets with same size, merge them. There will be at most $\log(n)$ disjoint sets.

Matrix exponentiation optimization. Save binary power of $A_{n \times n}$ and answer q queries $b = A^m x$ in $O((n^3 + qn^2)\log(m))$.

Ternary search on integers into binary search, comparing $f(\text{mid})$ and $f(\text{mid}+1)$, binary search on derivative

Dynamic offline set For each element we will wind segment of time $[a, b]$ such that element is present in the set during this whole segment. Now we can come up with recursive procedure which handles $[l, r]$ time segment considering that all elements such that $[l, r] \subset [a, b]$ are already included into the set. Now, keeping this invariant we recursively go into $[l, m]$ and $[m+1, r]$ subsegments. Finally when we come into segment of length 1.

$$a > b \implies a \bmod b < \frac{a}{2}$$

Convex Hull. The expected number of points in the convex hull of a random set of points is $O(\log(n))$. The number of points in a convex hull with points coordinates limited by L is $O(L^{2/3})$.
